Abstract

When plants recognize potential opponents, invading pathogens, wound signals, or abiotic stress, they often switch to a primed state of enhanced defense. However, defense priming can also be induced by some natural or synthetic chemicals. In the primed state, plants respond to biotic and abiotic stress with faster and stronger activation of defense, and this is often linked to immunity and abiotic stress tolerance. This review covers recent advances in disclosing molecular mechanisms of priming. These include elevated levels of pattern-recognition receptors and dormant signaling enzymes, transcription factor HsfB1 activity, and alterations in chromatin state. They also comprise the identification of aspartyl-tRNA synthetase as a receptor of the priming activator β -aminobutyric acid. The article also illustrates the inheritance of priming, exemplifies the role of recently identified priming activators azelaic and pipecolic acid, elaborates on the similarity to defense priming in mammals, and discusses the potential of defense priming in agriculture.

ABSTRACT

El Ghaouth, A., Arul, J., Grenier, J., and Asselin, A. 1992. Antifungal activity of chitosan on two postharvest pathogens of strawberry fruits. Phytopathology 82:398-402.

Effect of chitosan coating on decay of strawberry fruits held at 13 C was investigated. Strawberry fruits were inoculated with spore suspensions of Botrytis cinerea or Rhizopus stolonifer and subsequently coated with chitosan solutions (10 or 15 mg/ml). After 14 days of storage, decay caused by B. cinerea or R. stolonifer was markedly reduced by chitosan coating. Decay was not reduced further when the concentration of chitosan coating was increased from 10 to 15 mg/ml. Coating intact strawberries with chitosan did not stimulate chitinase, chitosanase, or β -1,3-glucanase activities in the tissue as revealed by polyacrylamide gel

assays. Chitosan, when applied on freshly cut strawberries, however, stimulated acidic chitinase activity. Chitosan was very effective in inhibiting spore germination, germ tube elongation, and radial growth of B. cinerea and R. stolonifer in culture. Furthermore, chitosan at a concentration greater than 1.5 mg/ml induced morphological changes in R. stolonifer. Mechanisms by which chitosan coating reduced the decay of strawberries appear to be related to its fungistatic property rather than to its ability to induce defense enzymes such as chitinase, chitosanase, and β -1,3-glucanase.

Chitin related food science today (and two centuries ago)

CORRADO MUZZARELLI RICCARDO A.A. MUZZARELLI

Polytechnic University of Marche, Institute of Biochemistry, Via Ranieri 67, IT-60100 Ancona, Italy

THE DISCOVERY OF CHITIN (IN A BOTANIC GARDEN).

In 1807 Henry Braconnot was appointed director of the Botanic Garden and Professor of Natural History in Nancy. The four-century old University of Nancy, as well as the University of Strashourn, hard heen sunnressed by the Assemblée Générale. and in Nancy the Medical School and the Academy were the only learned structures. Actually, the Garden and the Chair were part of the Medical School because of the interest in officinal plants. Those years were crucial for the connections between botany, hemistry and medicine. For example, morphine was isolated by Serturner in 1806, guinine was discovered by Pelletier and Caventon in 1823 and atropine was crystallized in 1833. The discovery of the anaesthetic action of nitrous oxide, diethyl ether and chloroform started a revolution in surgery. Braconnot had access to very modest means for doing research, also due to the continental embargo consequent to the Napoleon's wars. Nevertheless, while taking care of the heavily damaged Garden discovered chitin in 1811 started large scale cultivation of the sugar beet and the extraction and purification of sugar with the intention of alleviating food shortage. This activity was abruptly put to an end by the changed political situation which permitted to import sugar from tropical countries. He went on, however, with his idea of extracting sugars from plants and remarkably anticipated the modern approaches by directing attention to Heliantus tuberosus from

Braconnot was interested in the definition of the nutritional value of mushrooms. Braconnot wrote that poor countrymen considered mushrooms a manna given free as a gift of providence, and eagerly waited for the mushroom seasons. Today Agaricus bisyons is widely cultivated.

Systematic sulfuric acid treatment of a large number of substances led him to isolate two amino acids, glycine and leucine, in 1820. This discovery brought a certain renown to him. The direction of the Garden and the relevant problems (risky use of gas for healing the hothouses, fights against military plans to build casems inside the Garden) prevented Braconnot from exploiting his chemical discoveries. He was a precursor of Chevreul with his studies on fats, but he had no means to identify the fatty acids: he brought forward the idea of plant alkali but he could not isolate the alkaloids.

On the theoretical ground, he expressed the view that hydrogen and oxygen together with fire were the fundamental constituents of the universe, and plants can produce a number of elements from light and water.

Bracomiot published 112 papers in the form of memoirs of the Academy of Sciences. Letters and Arts of Nancy, also known as Academy of Stanislas, the King of Polish origin who ruled the Lorraine region. Other publications are in the Annales de Chimie et Physique and Journal de Chimie Medicale. He was also appointed corresponding member of the national Académie de Sciences, after Wollaston.

Braconnot certainly was an eminent chemist, as D.A. Godron, his successor, wrobe but he profused many energies in botany. Actually his teaching was according to Linnée, in a time period when novel theories on cellular structure, plant sexuality and atternate generations were being brought forward, as a consequence of the studies done on enormous collections of previously unknown plants, for instance the Filinders expedition (1801) made available 4000 unknown species of plants from Australia. In 1852 the 14,100 m² Garden had 3452 plants species, including some from New Zealand and Reunion Island provided by Empress Josephine. Braconnot took into account the novel views in botany, but dimmed sight forced him to refrain from teaching for several years before retirement. He left everything to the City of Nancy.

The discovery of chitin was essentially based on some reactions carried out on raw material isolated from Agaricus volvaceus, A. acris, A. cantarellus, A. piperatus, Hydnum repandum, H. hybridum and Boletus viscidus.

The existence of chilosan in nature remained unknown until 1954, when it was discovered in the yeast Phycomyces blakesleeanus. Chilosan occurs as the major structural component of the cell walls of certain fungl, mainly of the 2ggomycets species. However, to date, chilosans have been commercially produced by alkaline deacetylation of crustacean chiltris.

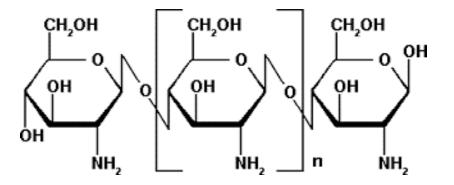

MODERN APPLICATIONS OF CHITOSAN IN FOOD SCIENCES

Antibacterial Activity

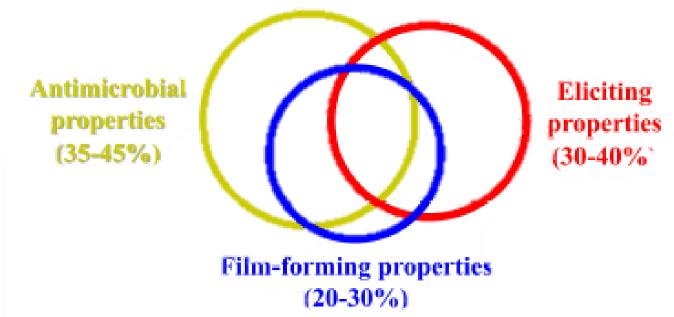

The antibacterial activity of chitosan was originally documented by Muzzarelli et al. (1990) who published electron micrographs showing the alterations produced in the bacterial cell wall and organelles. Those results were brilliantly confirmed more than a decade later by Helander et al (2001). Chemical and electrophoretic analyses of cell-free supernatants of chitosar treated cell suspensions showed that interaction of chitosan with E. coli and the salmonellae involved no release of lipopolysaccharide or other membrane lipids. Highly cationic the parent strains. Electron microscopy showed that chitosan caused extensive cell surface alterations and covered the oute membrane with vesicular structures. Chitosan thus appeared to bind to the outer membrane, explaining the loss of the barrier (Helander et al., 2001). It was also found that the antibacterial activity of quaternized chitosan against E. coli is stronger than that of chitosan (Jia et al., 2001) The antibacterial activity may be either bactericidal or

What's chitosan?

Chitosan is a natural biopolymer obtained from deacetylation of crab shells or extracted from fungi (e.g. *Aspergillus* sp.) with threefold activity

Effects of Pre- and Postharvest Chitosan Treatments to Control Storage Grey Mold of Table Grapes

G. ROMANAZZI, F. NIGRO, A. IPPOLITO, D. DI VENERE, AND M. SALERNO

ABSTRACT: The effectiveness of pre- and postharvest treatments with chitosan (0.1, 0.5, and 1.0%) to control Botrytis cinerea on table grapes was investigated. In postharvest treatments, small bunches dipped in chitosan solutions and inoculated with the pathogen showed a reduction of incidence, severity, and nesting of grey mold, in comparison with the control. Single berries artificially wounded, treated with the polymer, and inoculated with B. cinerea showed a reduced percentage of infected berries and lesion dia. Higher chitosan concentrations demonstrated greater decay reduction. All preharvest treatments significantly reduced the incidence of grey mold, as compared to the control. Table grapes treated with 1.0% chitosan showed a significant increase of phenylalanine ammonia-lyase (PAL) activity. Consequently, besides a direct activity against B. cinerea, chitosan produces other effects contributing to reduce decay.

Keywords: Botrytis cinerea, postharvest decay, PAL activity, sulphur dioxide, microflora

Introduction

Ulosses of table grapes in the field and is a major obstacle to lalanine ammonia-lyase (PAL) activity of the treated berries was their long-distance transport and storage. The pathogen is able evaluated. to develop at low temperature, shortening the length of storage and marketing (Ippolito and others 1998). In Italy, no synthetic fungicides are licensed to control decay of table grapes after harvest; sulphur dioxide is permitted as an adjuvant and is effective Fruits in reducing grey mold development during storage, However, aldifficulties in using SO₂ with colored grapes (Nelson and Richardson 1967). Considerable progress has recently been made in developing alternatives to synthetic fungicides for the control of postharvest diseases of fruit and vegetables (Wilson and Wis- Pathogens niewski 1994; Schena and others 1999; Ippolito and Nigro 2000; such as chitosan, a high molecular weight cationic polysacchabeen considered as a valid alternative. In fact, chitosan is an ideprolongs storage life and controls decay of strawberries (El Gha-(Zhang and Quantick 1997), and apples (Du and others 1998). Chitosan reduces the growth of many phytopathogenic bacteria and fungi (Allan and Hadwiger 1979). Moreover, it elicits phytoalexin formation (Reddy and others 1999) and induces the production of antifungal hydrolases (Fajardo and others 1998; Zhang and Quantick 1998; Hirano 1999). Chitosan has generally been applied in postharvest treatments (Baldwin and others 1995; Cheah and others 1997), and there are very few examples of pre-

Applications of chitosan alone, alternated or combined with copper for grapevine downy mildew management in large scale trials

Highlights

- Chitosan treatments controlled grapevine downy mildew on leaves and bunches.
- Starting chitosan application at flowering reduced copper residues in grape juice.
- · Chitosan showed a higher effectiveness in protecting bunches than leaves.
- Starting season with copper then applying chitosan was as effective as copper alone.
- Combination of low rates of chitosan and copper was more effective than copper alone.

Grapevine downy mildew reductions compared to untreated control

ABSTRACT

Janisiewicz, W. J., Takeda, F., Glenn, D. M., Camp, M. J., and Jurick, W. M., II. 2016. Dark period following UV-C treatment enhances killing of *Botrytis cinerea* conidia and controls gray mold of strawberries. Phytopathology 106:386-394.

Strawberries are available throughout the year either from production in the field or from high and low tunnel culture. Diversity of production conditions results in new challenges in controlling diseases before and after harvest. Fungicides have traditionally been used to control these diseases; however, their limitations necessitate a search for new approaches. We found that UV-C irradiation of *Botrytis cinerea*, a major pathogen of strawberry, can effectively kill this fungus if a dark period follows the treatment. The inclusion of a 4-h dark period resulted in almost complete kill of *B. cinerea* conidia on agar media at a dose of 12.36 J/m². The UV-C dose did not cause a reduction in photosynthesis in strawberry leaves or

discoloration of sepals, even after exposing plants repeatedly (twice a week) for 7 weeks. Although irradiation of dry conidia of *B. cinerea* with this dose resulted in some survival, the conidia were not infective and not able to cause decay even when inoculated onto a highly susceptible mature apple fruit. Irradiation of strawberry pollen at 12.36 J/m² did not affect pollen germination, tube growth and length in vitro, or germination and tube growth in the style of hand-pollinated emasculated strawberry flowers. No negative effect of the UV-C treatment was observed on fruit yield and quality in high tunnel culture. In the fruit and flower petal inoculation tests, the UV-C treatment was highly effective in reducing fruit decay and petal infection. This UV-C treatment with an exposure time of 60 s may be useful in controlling gray mold in tunnel production of strawberries and may also have the potential for use in intensive field and indoor production of other fruits and vegetables providing that a 4-h dark period follows the irradiation.

TABLE 6. Incidence of gray mold on strawberry fruit that were wounded and inoculated with either sterile tap water (STW) or suspension of *Botrytis cinerea* and irradiated with UV-C (254 nm) for various times followed by a 4-h dark incubation

	Inci	Incidence of gray mold (%)								
Treatment	3 days	5 days	7 days							
STW	0.0 Ь ^у	0.0 Ъ	0.0 ь							
STW + 60 s UV-C	0.0 Ъ	0.0 Ь	0.0 Ъ							
B. cinerea	$25.0 \text{ a } (\pm 16.0)^{2}$	75.0 a (±8.3)	100.0 a							
$B.\ cinerea + 60\ s$										
UV-C	0.0 Ь	41.7 ab (±16.0)	50.0 ab (±9.6)							
$B.\ cinerea + 90\ s$										
UV-C	0.0 Ъ	0.0 Ь	0.0 ь							
B. cinerea + 120 s										
UV-C	0.0 Ь	0.0 Ь	0.0 Ъ							

^y Values followed by the same letter in the same column are not significantly different according to Sidak adjusted *P* values so that the experiment-wise error was 0.05.

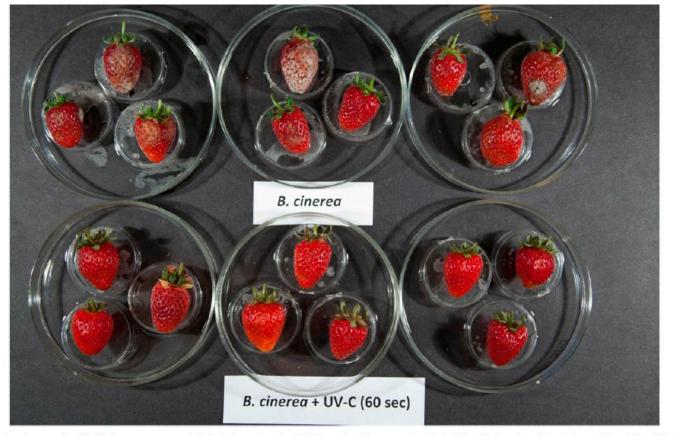

Fig. 2. Example of control of fruit decay on wounded fruit inoculated with *Botrytis cinerea* using UV-C irradiation for 60 s followed by 4 h of dark period and incubation for 5 days at 22°C.

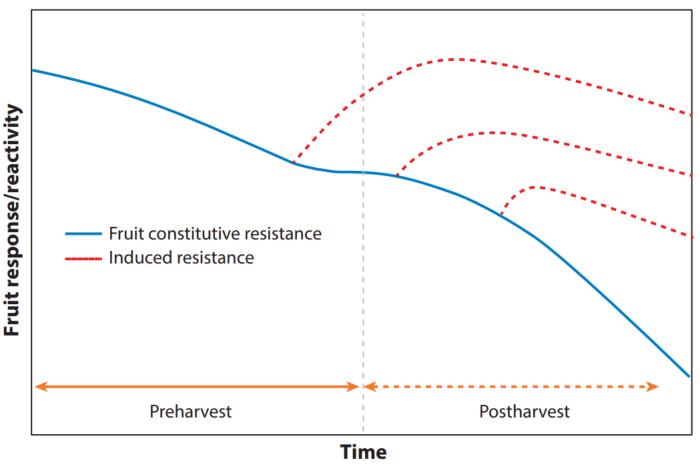

² Standard error of the mean of four replicates.

Supplementary Figure S1. Self-propelled UV-C irradiation apparatus with four irradiation units covering four raised beds with strawberry plants in high tunnel at the USDA-ARS Appalachian Fruit Research Station in Kearneysville, WV.

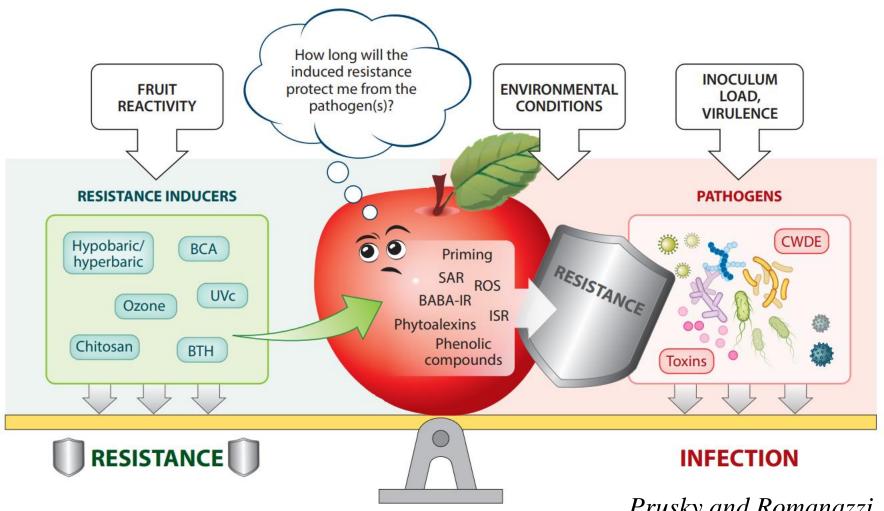

Keep high and eventually increase the resistance of plant tissues

Induced resistance needs to be applied at proper time

Keep high and eventually increase the resistance of plant tissues

Harvested fruit and vegetables are in a delicate dynamic equilibrium

Considerations

Table 5 Aspects related to the induction of resistance to postharvest diseases of fruit and vegetables.

Negative sides	Positive sides
Complete effect is not always reproducible	Long-lasting effects
Does not provide a complete control of decay	Broad range of targets
Not easy to implement as part of farmer and packinghouse practices	Do not cause appearance of resistant isolates of the pathogen
Investigation methods are not standardized	Increasing number of biostimulants on the market
	Low side effects
	Reduction of pesticide use
	Promoted by EU Directive n. 128/2009 «Sustainable Use of Pesticides» and following National Action
	Plans
	Increased amounts of beneficial antioxidant compounds

Induced resistance to prevent postharvest diseases

Thanks for your attention
